# Mixture Distribution

A distribution  $f$  is a mixture of  $K$  component distributions  $f_1, f_2, \dots, f_K$  if

$$f(x) = \sum_{k=1}^K \lambda_k f_k(x)$$

- $\lambda_k$  represent mixing weights
- $\lambda_k > 0$
- $\sum_k \lambda_k = 1$

# Parametric Mixture Models

Assuming  $f_k$  are all from the same parametric distributions the mixture model becomes:

$$f(x) = \sum_{k=1}^K \lambda_k f(x; \Theta_k)$$

- $\Theta_k$  is the parameter vector of the  $k^{th}$  component  $f_k$ .
- Vector of parameters of the mixture model is  $\Theta = (\lambda_1, \dots, \lambda_k, \Theta_1, \dots, \Theta_k)$

# Why Mixture Models

- A flexible approach to model complex distributions
- When  $K = 1$  we are back to parametric estimation
- As number of components  $K$  increases, the distribution tends to move from parametric to non-parametric representation
- A reasonable  $K$  which is usually small than the number of data points provides a good approximation of a semi-parametric density
- An approach for probabilistic clustering, with  $K$  denoting the number of clusters

The following figure shows various density functions of Gaussian mixtures with  $k = 2$  components (first row),  $k = 5$  components (second row),  $k = 25$  components (third row) and  $k = 50$  components (fourth row):

# Latent Variable Point of View

- Introduce a latent variable  $Z$
- $Z$  represents the class membership of the random variable  $X$ .  
Then,

$$\begin{aligned} Z &\sim \text{Multinomial}(\lambda_1, \lambda_2, \dots, \lambda_k) \\ f(X|Z = k) &= f(x; \Theta_k) \end{aligned}$$

# Graphical Model Representation of Mixture of Gaussians

- $f_k$ s have Gaussian or Normal distribution with different means and variances
- Nodes represent random variables
- Colored node is an observed random variable
- Symbols outside the box are parameters
- Edges represent direction of dependence

# Maximum Likelihood Estimation

$$l = \log p(X|\lambda, \mu, \Sigma) = \sum_{n=1}^N \log \sum_{k=1}^K \lambda_k \text{Normal}(x_n|\mu_k, \Sigma_k)$$

- No closed form solution maximizing the likelihood!

# Maximum Likelihood Estimation

$$\frac{\delta l}{\delta \Theta_i} = \sum_{n=1}^N \frac{\lambda_j f(x_i; \Theta_j)}{\sum_k \lambda_k f(x_i; \Theta_k)} \frac{\delta \log f(x_i; \Theta_j)}{\delta \Theta_j}$$

Define:  $w_{ij} = \frac{\lambda_j f(x_i; \Theta_j)}{\sum_k \lambda_k f(x_i; \Theta_k)} = P(Z_i = j | X_i, \Theta_i)$

# Parameter Estimation by Iterative Algorithms

- ① Expectation Maximization
- ② Sampling from posterior distribution

# Expectation Maximization

- Initialization: Start with guesses about the mixture components  $\Theta_1, \Theta_2, \dots, \Theta_K$  and the mixing weights  $\lambda_1, \dots, \lambda_K$
- Until convergence, iteratively
  - ① E-step: Using the current parameter guesses, calculate the weights  $w_{ij} = \frac{\lambda_j f(x_i; \Theta_j)}{\sum_{k=1}^K \lambda_k f(x_i; \Theta_k)}$
  - ② M-step: Using the current weights maximize the weighted likelihood to get new parameter estimates
- Return the final parameter estimates and cluster probabilities

# Sampling from Posterior Distribution

$$\begin{aligned}f(X|Z = k) &= \text{Normal}(\mu_k, \Sigma_K) \\Z &\sim \text{Multinomial}(\lambda_1, \lambda_2, \dots, \lambda_K) \\ \mu_k &\sim \text{Normal}(0, \sigma_0^2) \\ \Sigma_k &\sim \text{Inverse-Wishart}(a, b) \\ \lambda_1, \dots, \lambda_K &\sim \text{Dirichlet}(\alpha, K)\end{aligned}$$

Goal is to sample from the posterior distribution  $p(\lambda, \mu, \Sigma|X)$ .

# Markov Chain Monte Carlo Algorithm

- 1 Initialize  $\mu^0, \Sigma^0, \lambda^0$
- 2 Update  $Z$  sampling from  $Z^{(j+1)} \sim Z|x, Z^{(j)}, \lambda^{(j)}, \mu^{(j)}, \Sigma^{(j)}$
- 3 Update  $\mu$  sampling from  $\mu^{(j+1)} \sim \mu|x, Z^{(j+1)}, \lambda^{(j)}, \mu^{(j)}, \Sigma^{(j)}$
- 4 ...
- 5  $j = j+1$ . Go to step 2.

By iteratively updating and sampling from the conditional distribution for each parameter, we can sample from the joint posterior distribution of the parameter given data.

# Sampling from the Posterior

- Gibbs sampling
- Metropolis-Hastings sampling
- Metropolis with Gibbs sampling
- Computationally more expensive than analytical approaches

# How to Choose $K$

- $K$  or number of components in the mixture model needs to be pre-specified
- Classic problem in clustering or unsupervised learning
- Few ways to choose  $K$
- Fit mixture models with a range of values for  $K$ 
  - ① Cross-validation: Train on a subset of data and compute likelihood on test data
  - ② Choose  $K$  that maximizes information criteria
  - ③ Examples are: AIC, BIC or DIC

# Topic Modeling

- $K$  = specified number of topics
- $V$  = size of the vocabulary,  $D$  = number of document and  $N$  = words per document
- $\alpha$  = a positive vector of length  $K$
- $\nu$  is a scalar
- Topic proportions  $\theta$  are distributions over topic indices
- Topics  $\beta$  are distributions over the vocabulary

# Latent Dirichlet Allocation

(Blei et al., 2007)

# LDA

- ① For each topic, draw a distribution over words  $\beta_k \sim \text{Dirichlet}(\nu)$
- ② For each document,
  - ▶ Draw a vector of topic proportions  $\theta_d \sim \text{Dirichlet}(\alpha)$
  - ▶ For each word,
    - ★ Draw a topic assignment  
 $Z_{d,n} \sim \text{Multinomial}(\theta_d), Z_{d,n} \in \{1, \dots, K\}$
    - ★ Draw a word  $W_{d,n} \sim \text{Multinomial}(\beta_{Z_{d,n}}), W_{d,n} \in \{1, \dots, V\}$
